1. Introduction

1.1 Why this library exists

ph-pdf-layout sits on top of Apache PDFBox and provides a fluid, CSS-like box model so that callers can think in margins, padding and borders rather than in raw PDF content streams.

1.2 Document model

A PageLayoutPDF contains one or more PLPageSet instances; each page set groups elements that share a page size and margins. Elements flow top to bottom and split across pages automatically when they do not fit.

2. New in 8.2.0

2.1 Anchors and internal links

PLAnchor and the new IPLHasAnchorName interface let any element register a PDF named destination. PLInternalLink wraps another element and turns it into a clickable jump to such a destination - much like an HTML <a href="#id">.

2.2 PDF outlines (bookmarks)

PLOutlineBuilder collects a tree of (title, elementID) pairs and turns them into a PDF document outline. It implements IPLRenderListener so it captures element positions during rendering, and IPDDocumentCustomizer so the outline tree is written into the document right before save.

3. Conclusion

With named destinations, internal links and document outlines, ph-pdf-layout 8.2.0 makes long PDFs navigable without leaving the fluent layout API. Open this file in any modern PDF reader to see the outline panel populated and the table-of-contents entries become clickable.
